Basic logarithm and exponential relationships

Exponential and logarithm are related functions as expressed by $b = a^x$, where x is unknown power, a is the base (known), and b is the value resulting from a^x ($b > 0$). The expression that isolates x so x can be computed when a and b are known is:

$$x = \frac{\log(b)}{\log(a)} \quad (b > 0, a > 0, a \neq 1)$$

The restriction $a \neq 1$ applies because if $a = 1$ then the $\log(a) = 0$ generating an undefined value for x . Some of the properties related to logarithms and exponents are shown in the examples below.

Logarithm and exponential functions on the HP 30b

There are two exponent-related and one logarithm-related functions in the HP 30b, and the keys related to these functions are , , , and the common logarithm function, which is accessed by pressing , , , . The  function computes y raised to the x power while  computes e raised to the power of the number in the display (e is the Napier's number 2.718281828...).  computes the natural logarithm of the number in the display and , , ,  computes the common, base 10, logarithm of the number in the display.

Practice with solving logarithm and exponential problems

Example 1: Continuous compounding is often encountered in conversions from a nominal to an effective interest rate. The following expression is used:

$$EFF = e^{NOM} - 1$$

Figure 1

What is the effective annual rate equivalent to a nominal rate of 6%, compounded continuously?

Solution: The expression below represents the problem:

$$EFF = e^{0.06} - 1$$

Figure 2

The following keystroke sequence can be used to compute the effective rate:

In RPN mode:       
 In chain or algebraic mode:        

Answer: A nominal interest rate of 6%, compounded continuously is equivalent to an effective interest rate of 6.18%.

Example 2: When continuous compounding is considered in conversions from effective to nominal interest rate, the following expression is used:

$$NOM = \ln(EFF + 1)$$

Figure 3

What is the nominal interest rate, compounded continuously, equivalent to an effective interest rate of 6.18%?

Solution: The expression below represents the problem:

$$\text{NOM} = \ln(0.0618 + 1)$$

Figure 4

The following keystroke sequence can be used to compute the effective rate:

In RPN mode:

In chain or algebraic mode:

Answer: An effective interest rate of 6.18% is equivalent to a nominal interest rate of 6%, compounded continuously.

Example 3: Evaluate the following expressions and find x :

$$x = \sqrt[4]{81} \quad (1)$$

$$x = \log_3(20) - \log_3(5) \quad (2)$$

Solution: The original expression in (1) can be rewritten like this:

$$\sqrt[4]{81} = 81^{-(1/4)}$$

To find the solution, press:

In RPN mode:

In chain or algebraic mode:

In expression (2), the following sequence can be used:

In RPN mode:

In chain or algebraic mode:

Answer: The answers are:

(1) 0.33, or 1/3.

(2) 1.26, or 1.2618595
